

The paragraph below should be substituted for the last paragraph before section 6.3, on page 9 of "Weighted Multiple Regression Estimation for Survey Model Sampling."

J. Knaub

This methodology was next applied to generation values for utilities. In general, testing thus far indicates that using capacity as a second regressor may have very little impact on these utility cases, as the corresponding 'best' value for beta may be extremely small and often negative. Referring to equation (4.1), however, $(\beta_2 * c_i) / (\beta_1 * x_i)$ was generally fairly small in the above work on 'nonutilities,' yet using the second regressor, c_i , was very helpful in those cases.
